

# Timber Stand Improvement

## Overview

Timber stand improvement (TSI) is a complex but necessary endeavor for many landowners. Whether you are managing the land for timber production or wildlife, TSI has a place on your property.

More often than not, timber stands in Texas are overgrown and managed poorly. Sunlight does not reach the understory at levels that promote growth of valuable forage. The forests are infested by invasives, dominated by a select few species, and are littered with low value trees. Through proper TSI, these problems can be remediated; resulting in a productive understory, a reduction of undesirable species, and healthier desirable trees freed from competition.

If a timber management plan is currently in place for the property, our TSI work will follow the guidelines as designated. If you do not currently have a timber management plan, Wildland Systems Consulting is available to form one custom to your property with your goals in mind.

After determining your objectives, we will implement TSI practices while taking a targeted approach in order to reach your goals. TSI practices may include chainsaw work, brush hogging, herbicide application or other methods.
